

Statistical Physics: Weekly Problem 4 (SP4)

- (1) Consider an assembly of N weakly-interacting, distinguishable particles contained in a fixed volume V , with fixed internal energy U . Are the various distributions $\{n_i\}$ of the particles in single-particle states equally probable, or do they have different probabilities? State briefly what distinguishes the Boltzmann distribution from other distributions $\{n_i\}$ of the assembly of distinguishable particles. [2 marks]
- (2) A paramagnetic solid consists of N ions with spin $1/2$ and magnetic moment μ_B . The system lies in a magnetic field B and each magnetic moment is oriented either parallel to the field (up), with energy $\epsilon_\uparrow = -\mu_B B$, or antiparallel (down) with energy $\epsilon_\downarrow = +\mu_B B$. The system is in contact with a heat bath at temperature T .
- (a) Write down the single-particle partition function Z_1 followed by the probability p_\uparrow that a magnetic moment is up and the probability p_\downarrow that it is down. [1 mark]
- (b) The magnetisation per ion is equal to the average magnetic moment

$$M/N = \sum_i p_i m_i,$$

where $i = \uparrow, \downarrow$ and $m_\uparrow = \mu_B$, $m_\downarrow = -\mu_B$. Show that the magnetisation per ion is given by

$$\frac{M}{N} = \mu_B \tanh\left(\frac{\mu_B B}{k_B T}\right)$$

where k_B is Boltzmann's constant. [2 marks]

- (c) Obtain the internal energy U of the system of ions, directly from the definition,

$$U = N \sum_i p_i \epsilon_i.$$

Compare this with the energy of N magnetic moments, each of magnitude M/N , (b) above, and oriented along B . [2 marks]

- (d) (i) Using Gibbs' definition

$$S = -Nk_B \sum_i p_i \ln p_i,$$

show that the entropy of the system depends on the magnetic field B and on the temperature T through the ratio B/T . [1 mark]

- (ii) Sketch the graph of the entropy versus temperature for two different applied magnetic fields and then explain how a dilute paramagnetic solid can be cooled. [2 marks]
